Problem 1.3. b) By Power of a Point (Problem 1.1) we have $|O N| \cdot|O M|=|O A|^{2}=r^{2}$, so each orthogonal circle is fixed under inversion.

c) Lines through $O$, the center of $\omega$, are mapped to themselves. Now consider the case when the line $\ell$ is outside the circle of inversion. Drop the foot from $O$ to $A$. Invert $A$

about the circle to obtain $A^{\prime}$. Then construct the circle $\Gamma$ going through $O$ and $A^{\prime}$ with radius $\left|O A^{\prime}\right| / 2$. Let $P$ be a point on $\ell$ and let $P^{\prime}$ be the intersection of the line through $O P$ with $\Gamma$. We must show $\left|O P^{\prime}\right||O P|=r^{2}$. We have $O P^{\prime} A^{\prime} \sim O A P$ so

$$
\frac{\left|O P^{\prime}\right|}{|O A|}=\frac{|O A|}{|O P|} \Longrightarrow\left|O P^{\prime}\right||O P|=|O A|^{2}
$$

The same argument shows a circle through the center of $\omega$ is mapped to a line outside $\omega$.
Now suppose the line intersects $\omega$. The same argument works.

Now consider the case of a circle $\Gamma$ outside of the circle of inversion $\omega$.

Draw the line through the centers $O$ and $O_{2}$. Let $A$ and $B$ be the intersections of this line with $\Gamma$. We construct a circle $\Gamma^{\prime}$ as follows: Invert $A$ and $B$ about $\omega$ to $A^{\prime}$ and $B^{\prime}$ respectively and construct the circle through $B^{\prime}$ and $A^{\prime}$ with radius $\left|B^{\prime} A^{\prime}\right| / 2$. Now let $P$ be a point on $\Gamma$. It suffices to show the inversion $P^{\prime}$ of $P$ is on $\Gamma^{\prime}$. To that end construct the line through $O$ and $P$. Let $Q$ be its intersection with $\Gamma$ and $Q^{\prime}$ its intersection with $\Gamma^{\prime}$. Now $O A^{\prime} P^{\prime} \sim O B Q$. Note that $\angle A P Q=\angle O B Q$ since they subtend the same arc. Thus $O A^{\prime} P \sim O P A$, so we get

$$
\frac{\left|O A^{\prime}\right|}{\left|O P^{\prime}\right|}=\frac{|O P|}{|O A|} \Longrightarrow\left|O P \| O P^{\prime}\right|=|O A|\left|O A^{\prime}\right|=r^{2}
$$

Problem 1.5. By 1.4 we can construct a circle $\Gamma$ so that the inversion of $A$ about $\Gamma$ is $O$. Now invert $B$ about $\Gamma$ and let its image be $B^{\prime}$. Construct the line through $O$ and $B^{\prime}$. Inverting this line about $\Gamma$ gives us a circle going through $A$ and $B$.

This circle is orthogonal to $\omega$ because the line $O B^{\prime}$ is orthogonal to $\omega$.
Problem 1.6. First suppose the first line $\ell_{1}$ goes through $O$. Let the second line $\ell_{2}$ intersect $\ell_{1}$ outside the circle at an angle $\alpha$. The inversion of $\ell_{2}$ about $\omega$ is a circle $\Gamma$ passing through $O$. The inverted angle $\beta$ is the angle of intersection of $O A$ and the tangent to $\Gamma$ at $A^{\prime}$. We have $O A^{\prime} P^{\prime} \sim O P A$ so $\angle O A P=\angle O P^{\prime} A^{\prime}=\alpha$. But $\beta$ subtends the same arc of $\Gamma^{\prime}$ so $\alpha=\beta$ (this theorem works even for tangent lines).

For case where $\ell_{1}$ and $\ell_{2}$ do not go through the origin, just note that when we invert them about $\omega$ and construct the tangent lines, these tangent lines are parallel to $\ell_{1}$ and $\ell_{2}$ respectively.

Problem 1.8. Assume $A$ and $C$ are not colinear (this case follows easily). If $A^{\prime}$ and $C^{\prime}$ are the images of $A$ and $C$ respectively, then $O A B \sim O B^{\prime} A^{\prime}$. Therefore $\frac{|A C|}{\mid A C^{\prime} C^{\prime}}=\frac{|O A|}{\left|O C^{\prime}\right|}$ The same argument gives us the analgous statement for $B C, B D$, and $A D$. Thus the cross ratio becomes

$$
\frac{|A C|}{\left|A^{\prime} C^{\prime}\right|} \frac{\left|B^{\prime} C^{\prime}\right|}{|B C|} \frac{|B D|}{\left|B^{\prime} D^{\prime}\right|} \frac{\left|A^{\prime} D^{\prime}\right|}{|A D|}=1
$$

Rearranging we obtain $[A, B ; C, D]=\left[A^{\prime}, B^{\prime} ; C^{\prime}, D^{\prime}\right]$.

Problem 2.3. e) We assume $P$ and $Q$ are ordered so that $|O P| \leq|O Q|$ and $|A P| \geq|A Q|$. We have

$$
\log \left(\frac{|A P||O Q|}{|O P||A Q|}\right)=\log \frac{1+r}{1-r}
$$

Remark: the last quantity is actually given in terms of the hyperbolic tangent function $2 \tanh ^{-1} r$ defined by

$$
\tanh x=\frac{e^{x}-e^{-x}}{e^{x}+e^{-x}}=\frac{1-e^{-2 x}}{1+e^{-2 x}}
$$

Problem 2.9. WLOG we take $\ell$ to be the diameter of $\mathbb{D} . X_{1} R P$ is isosceles since its

sides are the tangents to the circle going through $P$. Since $\angle X_{1} O P=\pi / 2$ we have $2 \alpha+$ thet $a=\pi / 2$ or $\alpha=\pi / 4-\theta / 2$. Now we calculate

$$
d=d(0, P)=\tan \alpha=\tan \left(\frac{\pi}{4}-\frac{\theta}{2}\right)=\frac{1-\tan (\theta / 2)}{1+\tan (\theta / 2)}
$$

exponentiating and using 2.3 e) we get

$$
e^{d}=\frac{1+\tan \alpha}{1-\tan \alpha}=\frac{1}{\tan \theta}
$$

Hence $e^{-d}=\tan (\theta / 2)$.
